```

7. R also comes with a set of boolean operators that you can use to combine multiple logical tests into a single test. These include & (and), | (or), and ! (not). Instead of using the & operator, you can also pass several logical tests to `filter()`, separated by commas. `is.na()` will also come in handy.

- Use R's logical and boolean operators to select just the rows in your data that meet a specific boolean condition.
- Print out all of the observations in your data in which none of variables are NA. Selecting only male and people with actual prison time (below 9000).

```
filter(test, MONSEX == "Male" & TOTPRISN < 9000)
```

```

8. `arrange()` can be used to rearrange rows according to any type of data. If you pass `arrange()` a character variable, for example, R will rearrange the rows in alphabetical order according to values of the variable. If you pass a factor variable, R will rearrange the rows according to the order of the levels in your factor (running `levels()` on the variable reveals this order).

By default, `arrange()` arranges the rows from smallest to largest. Rows with the smallest value of the variable will appear at the top of the data set. You can reverse this behavior with the `desc()` function. `arrange()` will reorder the rows from largest to smallest values of a variable if you wrap the variable name in `desc()` before passing it to `arrange()`.

- Which variable(s) in your dataset would be logical to arrange your data on? Explain your reasoning.
- Arrange your data by this/these variables and print the results.

My data would best be arranged by the year, because it will eventually be a panel data. I won't do it here because it's not merged yet, but if I bind it in the right order of years I shouldn't need to use this. I will arrange it by the prison time here to practice.

```
arrange(test, TOTPRISN)
```

```
##      X.1      X      MONRACE YEAR

```

9. You can use any function you like in `summarise()` so long as the function can take a vector of data and return a single number. R contains many aggregating functions, as `dplyr` calls them:

- `min(x)` - minimum value of vector `x`.
- `max(x)` - maximum value of vector `x`.
- `mean(x)` - mean value of vector `x`.
- `median(x)` - median value of vector `x`.

- `quantile(x, p)` - pth quantile of vector `x`.
  - `sd(x)` - standard deviation of vector `x`.
  - `var(x)` - variance of vector `x`.
  - `IQR(x)` - Inter Quartile Range (IQR) of vector `x`.
  - `diff(range(x))` - total range of vector `x`.
- Pick at least one variable of interest to your project analysis. Mode of the type of case (guilty plea, trial, dismissal...etc.), level of education of the defendant, and age.
  - Print out at least three summary statistics using `summarise()`.

*# Create a mode function:*

```
getmode <- function(v) {
  uniqv <- unique(v)
  uniqv[which.max(tabulate(match(v, uniqv)))]
}
```

*# now summarise using 'getmode()' function*

```
summarise(test, getmode(test$DISPOSIT),
            getmode(test$EDUCATN),
            getmode(AGE))
```

```
##   getmode(test$DISPOSIT) getmode(test$EDUCATN) getmode(AGE)
## 1                Guilty plea High school graduate          25
```

- `dplyr` provides several helpful aggregate functions of its own, in addition to the ones that are already defined in R. These include:

- `first(x)` - The first element of vector `x`.
- `last(x)` - The last element of vector `x`.
- `nth(x, n)` - The nth element of vector `x`.
- `n()` - The number of rows in the data.frame or group of observations that `summarise()` describes.
- `n_distinct(x)` - The number of unique values in vector `x`.

Next to these `dplyr`-specific functions, you can also turn a logical test into an aggregating function with `sum()` or `mean()`. A logical test returns a vector of TRUE's and FALSE's. When you apply `sum()` or `mean()` to such a vector, R coerces each TRUE to a 1 and each FALSE to a 0. `sum()` then represents the total number of observations that passed the test; `mean()` represents the proportion.

- Print out a summary of your data using at least two of these `dplyr`-specific aggregate functions.
- Why did you choose the ones you did? What did you learn about your data from these summaries?

```
test %>%
  filter(!is.na(TOTPRISN)) %>%
  summarise(last(TOTPRISN),
            n_distinct(DISTRICT))
```

```
##   last(TOTPRISN) n_distinct(DISTRICT)
## 1             28                94
```

- You can also combine `group_by()` with `mutate()`. When you mutate grouped data, `mutate()` will calculate the new variables independently for each group. This is particularly useful when `mutate()` uses the `rank()` function, that calculates within-group rankings. `rank()` takes a group of values and calculates the rank of each value within the group, e.g.

```
rank(c(21, 22, 24, 23))
```

has the output

```
[1] 1 2 4 3
```

As with `arrange()`, `rank()` ranks values from the smallest to the largest.

- a. Using the `%>%` operator, first group your dataset by a meaningful variable, then perform a mutation that you're interested in.
- b. What do the results tell you about different groups in your data?

I don't think this is applicable to my data.

12. The exercises so far have tried to get you to think about how to apply the five verbs of `dplyr` to your data.
  - a. Are there any specific transformations you want to make to your data? What are they and what aspect of your research question will they help you to answer?
  - b. In a code chunk below, carry out all the data transformations you wish to perform on your data. Utilize the `%>%` operator to tie multiple commands together and make your code more readable and efficient. Remember to comment your code so it is clear why you're doing things a certain way.

They are listed above. I will apply them to the 20 years of data that I have. See `mutate` script in my `scripts` folder.
